Fastener Steels

Alloy Steels: Steels alloyed with molybdenum, nickel and chromium (AISI 4037, 4130, 8630) are best where high strength is required. These steels have good cold forming properties in the annealed condition and can be heat-treated for the best combination of strength, toughness and shock resistance.

Aluminum Alloys: Good cold-forming characteristics. Many aluminum can be used (2024, 2003, 5056, 5054, 6061, and 7075), and where secondary machining is required (2011). Aluminum is corrosion resistant and some can be heat-treated.

Carbon Steels: Fine grain, fully-killed basic steel with no alloying agent. Low Carbon Steels: Range from 0.06-0.25% carbon content (AISI 1008, 1018) and have good ductility for cold forming. Medium Carbon Steels: Have 0.25-0.75% carbon content (AISI 1038, 1045). Stronger and less ductile, these steels respond well to quench and temper. High Carbon Steels: 0.75% carbon and up (AISI 1065, 1095). Difficult to cold form unless annealed. High strength, can be heat-treated.

Hard Drawn MB Spring Wire, ASTM A227: Carbon range 0.6-7.0%. Used for general purpose low-cost springs. Commonly available in diameters .031 to .500. Lower tensile strength than mild steel wire.

Leaded Steels: Lead added to steel improves machinability. Identified by an “L” (AISI 1214) in the AISI/SAE designation. This is most commonly added to 1000 and 1200 series ‘screw machine’ steels. Leaded steels are not suitable for heat treatment or welding.

Mechanical Definitions

Cold Working: Deformation of a metal at room temperature without fracture which changes its shape and produces higher tensile strength and machinability.

Ductility: The ability of a metal to be deformed extensively under tension load without rupture or fracture. Ductility is expressed in terms of percent elongation and percent reduction of area (e.g. drawn into wire).

Machinability: The condition or property of a metal which allows it to be cut, turned, broached or formed by machine tools.

Malleability: The ability of a metal to be deformed permanently under compression load without rupture or fracture (e.g. hammer or rolled into sheets).

Tensile Strength: The maximum load in tension (pulling apart or shearing) which a material can withstand before breaking or fracturing. Also known as the ultimate tensile strength (UTS) or maximum strength.

Work Hardening: Hardening that takes place through grain alignment when a metal is bent, rolled or hammered at room temperature. Not all metals work harden.

Yield Strength: The maximum load which a material exhibits a specific permanent deformation. Deformation to determine yield varies with material.

Process Definitions

Alloy Steel: A carbon steel to which one or more elements are added to add special properties for a specific use.

Billet: A cast section of steel 4 to 6 inches square about 20 ft. long from which dimensional shapes of steel are rolled.

Brass: An alloy of copper and zinc which can contain small amounts of aluminum, iron, manganese, or tin to produce specific properties.

Bronze: An alloy of copper and tin or an alloy of aluminum and silicon.

Carbon Steel: A steel in which carbon is the only alloying element added to iron.

Killed Steels: Molten steel treated with aluminum, silicon, or manganese until no more gas is in the steel and it is in a quiet state.

Pickling: The removal of oxide scale from metal by dipping it in a dilute acid bath. The chemically clean surface is then ready for cold rolling or wire drawing.

Rockwell Hardness Test: A method of determining metal hardness by indenting with a metal ball or diamond cone under a specified load.

Music Wire, ASTM A228: Carbon range 80-95%. High tensile strength can withstand repeated loading. Widely used in small diameter rounds .005 to .125.

Resulphurized and Rephosphorized Steels (AISI 1117 and 1215): Improved machinability over basic carbon steels. Used commonly for screw machine parts, they are more brittle, less ductile and stronger than equivalent carbon content basic steel. Sulphur acts as an internal lubricant and is the major alloying agent for “1100” series steels. Phosphorus makes the steel more brittle, reducing friction, heat and tool wear. “1200” series steels have both phosphorus and sulphur as alloys.

Stainless Steels

Austenitic Stainless Steels: (AISI 304, 303, 301, 316) Generally nonmagnetic and the best corrosion resistant due to their large content of nickel and chromium. Good cold-forming characteristics are subject to work hardening and are not heat treatable.

Martensitic Stainless Steel: Straight chromium steel with little or no nickel (AISI 410, 420). These steels are magnetic and can be heat-treated. Higher strength than austenitic types, lower corrosion resistance and harder to cold form.

Precipitation Hardening Stainless: (AISI 17-4 PH) Nickel chromium stainless with cobalt and tantalum. The alloying agents produce high strength and ductility, good machinability and weldability. Hardening is by aging the cold steel at 900°F for 4 hours followed by air-cooling. Not used for cold forming but commonly used for high-strength, corrosion resistant screw machine parts.

Mechanical Properties

Clevis Pin Definitions

Heat Treating Definitions

Annealing: Heating and slow cooling to remove stresses, make steel softer, refine the structure, or change its ductility.

Carburizing: Adding carbon to the surface of iron-based alloys by heating the metal below its melting point in contact with carbon-rich solids, liquids or gases.

Case Hardening: Carburizing a metal surface followed by quenching to fix a hard outer case high in carbon combined with a relatively soft middle or core.

Cyanide Hardening: A method of case hardening which brings the metal surface in contact with the molten cyanide salt followed by quenching.

Decarburization: Removal of carbon from the surface of steel. This can occur through normal oxidizing action or as a result of heat treatment.

Drawing (Tempering): Reheating after hardening, held at a specific temperature and then quenched. This reduces hardness and increases toughness.

Hydrogen Embrittlement: A condition where the surface finishing of metal (plating) results in a brittle outer case due to oxidation in acid. Baking immediately following the plating process removes this brittle surface condition.

Nitruring: A hardening process which adds nitrogen to a metal surface through contact with ammonia gas. Produces surface hardness (case) without quenching.

Precipitation Hardening: A hardening process wherein certain metals are held at elevated temperatures without quenching (age hardening).

Quenching: Rapid cooling of steel by immersion in oil or water to fix its structure in a hardened state.

Spheroidizing (or roundel): A process of heating and cooling steel that produces a rounded or globular form of carbide. This softens the metal, improving ductility.

Stress Relieve: A low temperature heat treatment, which removes stresses caused by cold working.
